BACKGROUND AND PURPOSE: As numerous questions remain about the best anesthetic strategy during thrombectomy, we assessed functional and radiological outcomes in stroke patients treated with thrombectomy in presence of general anesthesia (GA) versus conscious sedation (CS) and local anesthesia (LA).

METHODS: We conducted a cohort study on prospectively collected data from 4429 patients enrolled in the Italian Registry of Endovascular Treatment in Acute Stroke.

RESULTS: GA was used in 2013 patients, CS in 1285 patients, and LA in 1131 patients. The rates of 3-month modified Rankin Scale score of 0–1 were 32.7%, 33.7%, and 38.1% in the GA, CS, and LA groups: GA versus CS: odds ratios after adjustment for unbalanced variables (adjusted odds ratio [aOR]), 0.811 (95% CI, 0.602–1.091); and GA versus LA: aOR, 0.714 (95% CI, 0.515–0.990). The rates of modified Rankin Scale score of 0–2 were 42.5%, 46.6%, and 52.4% in the GA, CS, and LA groups: GA versus CS: aOR, 0.902 (95% CI, 0.689–1.180); and GA versus LA: aOR, 0.769 (95% CI, 0.566–0.998). The rates of 3-month death were 21.5%, 19.7%, and 14.8% in the GA, CS, and LA groups: GA versus CS: aOR, 0.872 (95% CI, 0.644–1.181); and GA versus LA: aOR, 1.235 (95% CI, 0.844–1.807). The rates of parenchymal hematoma were 9%, 12.6%, and 11.3% in the GA, CS, and LA groups: GA versus CS: aOR, 0.380 (95% CI, 0.262–0.551); and GA versus LA: aOR, 0.532 (95% CI, 0.337–0.838). After model of adjustment for predefined variables (age, sex, thrombolysis, National Institutes of Health Stroke Scale, onset-to-groin time, anterior large vessel occlusion, procedure time, prestroke modified Rankin Scale score of <1, antiplatelet, and anticoagulant), differences were found also between GA versus CS as

regards modified Rankin Scale score of 0–2 (aOR, 0.659 [95% CI, 0.538–0.807]) and GA versus LA as regards death (aOR, 1.413 [95% CI, 1.095–1.823]).

Cappellari et al General Anesthesia During Thrombectomy

2 July 2020 Stroke. 2020;51:2036–2044. DOI: 10.1161/STROKEAHA.120.028963

CONCLUSIONS: GA during thrombectomy was associated with worse 3-month functional outcomes, especially when compared

with LA. The inclusion of an LA arm in future randomized clinical trials of anesthesia strategy is recommended.

Key Words: anesthesia ■ conscious sedation ■ groin ■ odds ratio ■ thrombectomy

Mechanical thrombectomy for ischemic stroke with

large vessel occlusion substantially reduces disability, with 5 randomized clinical trials leading to guideline changes worldwide.^{1–5} However, numerous

questions remain about the best practices for mechanical thrombectomy, including which anesthetic strategy

results in the best clinical outcomes.

Two previous meta-analyses reported worse 3-month

functional outcomes from general anesthesia (GA) than

from nongeneral anesthesia (non-GA; composite of conscious sedation [CS] and local anesthesia [LA]) during

mechanical thrombectomy,^{6,7} while the rates of recanalization success and symptomatic intracerebral hemorrhage (sICH) did not differ.^{6,7}

In the last years, the interest has focused on the comparison between GA and CS during mechanical thrombectomy. CS is often considered as the ideal compromise

during mechanical thrombectomy by preserving patient

cooperation, comfort, and procedural speed compared with

LA and reducing medication levels compared with GA. A

recent meta-analysis reported that CS was associated with better 3-month functional outcome when compared with GA, while recanalization success and sICH were similar.⁸ Similarly, a DEFUSE 3 (Endovascular Therapy Following Imaging Evaluation for Ischemic Stroke) analysis showed that patients who underwent thrombectomy with CS in the extended time window experienced a higher likelihood of 3-month functional independence when compared with those who had GA.⁹ However, recently published randomized clinical trials (ie, SIESTA [Sedation vs Intubation for Endovascular Stroke Treatment], ANSTROKE [Anesthesia During Stroke], and GOLIATH [General or Local Anesthesia in Intra-Arterial Therapy])^{10–12} comparing GA and CS during mechanical thrombectomy have not confirmed the superiority of CS over GA.

On the other hand, a recently published study reported that CS was associated with poor functional outcome compared with LA.¹³ A few studies have also compared the functional outcome between patients treated with LA and GA. A multicenter retrospective registry study demonstrated that clinical outcomes and survival were significantly better in patients treated with LA than with GA.¹⁴ Similarly, data from The Interventional Management of Stroke III trial showed that GA was associated with worse neurological outcomes and increased mortality compared with LA.¹⁵ Recanalization success and sICH were similar between the 2 groups. However, the studies were limited by sample size.

The aim of this study was to assess functional and

radiological outcomes in a large cohort of large vessel occlusion–related acute ischemic strokes treated with mechanical thrombectomy in presence of GA versus non-GA, GA versus CS, and GA versus LA.

METHODS

Study Design, Participants, and Procedures

We conducted a cohort study on prospectively collected data of patients enrolled in the IRETAS (Italian Registry of Endovascular Treatment in Acute Stroke). The IRETAS is a multicenter, observational internet-based registry (Table I in the Data Supplement). Acute ischemic stroke patients with large vessel occlusion who received endovascular procedures between January 2011 and December 2017 were included in the present study. Participating centers were required to accept the rules of the IRETAS, including consecutive registration of all stroke patients receiving endovascular procedures irrespective of whether treatment was according to guidelines. Our analysis was conducted according to the STROBE criteria (Strengthening the Reporting of Observational Studies in Epidemiology) for observational studies.¹⁶

Data Collection

The clinical data were collected by neurologists, whereas the radiological data were collected by neuroradiologists of each center. Data collection is provided in the Supplementary Material in the Data Supplement. The choice of type of anesthesia (ie, GA, CS, LA) and anesthetic agents (ie, type, dosage) was at the discretion of the stroke team (neurologist, neuroradiologist, and

anesthesiologist) of each center according to the particular neurological and general conditions of the patient (eg, prehospital

tracheal intubation, level of consciousness, aphasia, neglect, dysphagia, agitation, aspiration, vomiting, respiratory failure) and the

habits/experience of the individual operator. GA was provided

for tracheal intubation and mechanical ventilation and was maintained according to local standards and protocols. CS had the

goal of reducing agitation, anxiety, and movements, but allowing

communication with the patient, and was performed according to

local standards and protocols. LA was achieved by subcutaneous

injection of anesthetic at the puncture site.

Inclusion and Exclusion Criteria

We included all patients with age ≥ 18 years who received

mechanical thrombectomy. We excluded patients who received

intra-arterial fibrinolysis alone and patients for lacking data on

type of anesthesia.

Cappellari et al General Anesthesia During Thrombectomy

Stroke. 2020;51:2036–2044. DOI: 10.1161/STROKEAHA.120.028963 July 2020 3

Outcome

The functional outcomes were (1) excellent functional outcome

(modified Rankin Scale score of 0–1), (2) favorable functional

outcome (modified Rankin Scale score of 0–2), and (3) death

at 3 months. The radiological outcomes were (1) successful

recanalization (Thrombolysis in Cerebral Infarction grading

system 2b/3), (2) complete recanalization (Thrombolysis in

Cerebral Infarction grading system 3) after the procedure, (3)

any type of intracerebral hemorrhage (ICH), (4) hemorrhagic infarct (HI), (5) parenchymal hematoma (PH), (6) subarachnoid hemorrhage, and (7) sICH (defined as PH with increase of ≥ 4 National Institutes of Health Stroke Scale score points from baseline or death) within 24 hours.

Statistical Analysis

We performed statistical analyses using SPSS 22.0 statistical package. Continuous variables were reported as median and interquartile range values. Proportions were calculated for categorical variables, dividing the number of events by the total number excluding missing/unknown cases. Statistical significance was established at 2-tailed 0.05 level ($P < 0.05$).

We estimated the associations of GA (versus non-GA, versus CS, and versus LA) on outcome measures by calculating the odds ratios (ORs) with 2-sided 95% CI after adjustment for group differences in baseline characteristics (probability value < 0.10), including variables with a number of missing values which was less than one-third of the entire cohort.

Propensity score matching of 2 similar groups (GA versus non-GA) was conducted with 1:1 ratio and match tolerance of 0.0005. Five models of propensity score matching were applied to the 2 groups of patients among the cohorts of patients with complete data for 3-month modified Rankin Scale score, Thrombolysis in Cerebral Infarction grading system, ICH, and sICH. The clinical and radiological predictors of the models were identified by 3 neurologists with clinical expertise in

the management of stroke according to recent literature.^{17–20}

Predictors with a number of missing values which was greater than one-third of the entire cohort were excluded. The first

Figure. Flow diagram of included and excluded patients. IA indicates intra-arterial; ICH, intracerebral hemorrhage; IRETAS, Italian Registry of Endovascular Treatment in Acute Stroke; mRS, modified Rankin Scale; and TICI, Thrombolysis in Cerebral Infarction.

Cappellari et al General Anesthesia During Thrombectomy

Stroke. 2020;51:2036–2044. DOI: 10.1161/STROKEAHA.120.028963 July 2020 5

model included age (18–49, 50–64, 65–79, or ≥80 years), sex,

National Institutes of Health Stroke Scale score (≤10, 11–15,

16–20, or >20), intravenous thrombolysis, and onset-to-groin

time (≤180, 181–360, or >360 minutes). The second included

variables of the first model plus large vessel occlusion in the

anterior circulation and procedure time (≤60 or >60 minutes).

The third model included variables of the second model plus

prestroke modified Rankin Scale score of <1, antiplatelet,

and oral anticoagulant. The fourth model included variables of

the third model plus side of occlusion and ASPECTS (Alberta

Stroke Program Early CT Score) of ≥6. The fifth model included

variables of the fourth model plus additional intra-arterial fibrinolysis and single thrombectomy device pass.

We calculated the ORs (95% CI) of GA (versus CS and

versus LA) for each outcome measure after the application of

5 models of adjustment including the same predefined variables of the 5 models of propensity score matching used for

GA versus non-GA.

Standard Protocol Approvals, Registrations, and

Patient Consents

Need for ethical approval or patient consent for participation

in the IRETAS varied among participating hospitals. Ethical

approval and informed consent were obtained when required.

Data Availability Statement

Anonymized data will be shared by request from any qualified investigator.

RESULTS

Among 5559 patients registered in the IRETAS cohort

by 44 centers (Table II in the Data Supplement), 4429

patients (n=2013, GA; n=2416, non-GA) were included

in the study. Flow diagram of patient inclusion and exclusion is provided in the Figure. The clinical characteristics of the GA (n=1881, GA started before procedure;

n=132, GA started during procedure after conversion

from CS or LA), CS (n=1285), and LA (n=1131) groups

are provided in Table 1.

Unbalanced variables between GA and non-GA

groups are provided in Table III in the Data Supplement.

After adjustment for unbalanced variables (age, sex,

years 2016–2017, diabetes mellitus, hyperlipidemia, current or past smoking, atrial fibrillation, coronary heart disease, antiplatelet, oral anticoagulant, National Institutes

of Health Stroke Scale score, ASPECTS, occlusion site,

intravenous thrombolysis, onset-to-groin time, type of procedure, single thrombectomy device pass, and procedure

time), a significant difference was found between GA and

non-GA groups as regards excellent functional outcome

(32.7% versus 35.8%; adjusted OR (aOR), 0.761 [95%

CI, 0.597–0.970]), favorable functional outcome (42.5%

versus 49.4%; aOR, 0.799 [95% CI, 0.640–0.996]), any

ICH (22.1% versus 28.4%; aOR, 0.584 [95% CI, 0.468–

0.729]), HI (11.7% versus 16%; aOR, 0.736 [95% CI,

VI in the Data Supplement); lower rates of any ICH, HI,

and PH according to the first (22.4% versus 30.7%,

$P<0.001$; 12% versus 17.4%, $P<0.001$; 9.2% versus

12.8%, $P=0.003$), the second (24.4% versus 30.6%, $P=0.001$; 13.8% versus 17.6%, $P=0.008$; 9.8% versus 12.6%, $P=0.032$), and the fourth (23.6% versus 33.1%, $P<0.001$; 14.2% versus 20.6%, $P=0.002$; 8.3% versus 12.6%, $P=0.010$) models (Tables VI, VII, and VIII in the Data Supplement); lower rates of excellent and favorable functional outcome according to the third (28.4% versus 33.1%, $P=0.030$; 40.1% versus 47.2%, $P=0.002$) and the fourth (27.7% versus 33.2%, $P=0.026$; 40.7% versus 46.8%, $P=0.020$) models (Tables VIII and IX in the Data Supplement); a lower rate of favorable functional outcome according to the fifth model (40.8% versus 50.8%, $P=0.028$) (Table X in the Data Supplement); a lower rate of any ICH according to the third (24.4% versus 29.3%, $P=0.018$) and the fifth (22.5% versus 30.3%; $P=0.049$) models (Tables IX and X in the Data Supplement); and a lower rate of HI according to the fifth model (12.7% versus 21%; $P=0.015$) (Table X in the Data Supplement).

After excluding 132 patients who started GA during the procedure, associations between GA (versus non-GA) and outcome measures after adjustment for unbalanced variables are provided in Table XI in the Data Supplement. Associations between GA (versus non-GA) and outcome measures after 5 models of adjustment for predefined variables are provided in Table XII in the Data Supplement. Unbalanced variables between GA and CS groups are provided in Table XIII in the Data Supplement. Unbalanced variables between GA and LA groups are provided in Table XIV in the Data Supplement. Associations between GA (versus CS and LA) and outcome

measures after adjustment for unbalanced variables are provided in Table 2. A significant difference was found between GA and CS groups as regards any ICH (22.1% versus 27.3%; aORs, 0.591 [95% CI, 0.452–0.773]) and PH (9% versus 12.6%; aORs, 0.380 [95% CI, 0.262–0.551]). A significant difference was found between GA and LA groups as regards excellent functional outcome (32.7% versus 38.1%; aOR, 0.714 [95% CI, 0.515–0.990]), favorable functional outcome (42.5% versus 52.4%; aOR, 0.769 [95% CI, 0.566–0.998]), any ICH (22.1% versus 29.5%; aOR, 0.539 [95% CI, 0.398–0.730]), HI (11.7% versus 17.8%; aOR, 0.561 [95% CI, 0.395–0.797]), and PH (9% versus 11.3%; aOR, 0.532 [95% CI, 0.337–0.838]).

Associations between GA (versus CS and LA) and outcome measures after 5 models of adjustment for predefined variables are provided in Table 3. A significant difference was found between GA and CS groups as regards HI (11.7% versus 14.4%) according to the first (aOR, 0.778 [95% CI, 0.620–0.978]) and the fifth (aOR, 0.691 [95% CI, 0.500–0.93]) models and favorable

functional outcome (42.5% versus 46.6%) according to the third (aOR, 0.768 [95% CI, 0.631–0.935]), the fourth (aOR, 0.800 [95% CI, 0.642–0.992]), and the fifth (aOR, 0.732 [95% CI, 0.556–0.962]) models. A significant difference was found between GA and LA groups as regards death (21.5% versus 14.8%) according to the first (aOR, 1.347 [95% CI, 1.075–1.686]), the second (aOR, 1.301 [95% CI, 1.032–1.641]), the third

(aOR, 1.413 [95% CI, 1.095–1.823]), and the fourth (aOR, 1.331 [95% CI, 1.005–1.762]) models. All models confirmed a significant difference between GA and CS groups as regards any ICH and PH. All models confirmed a significant difference between GA and LA groups as regards favorable functional outcome, any ICH, and HI. A significant difference was confirmed between GA and LA groups as regards excellent functional outcome according to the third, the fourth, and the fifth models, and with PH according to the first, the fourth, and the fifth models.

DISCUSSION

Our study showed that GA (versus non-GA) during mechanical thrombectomy was significantly associated with lower rates of excellent and favorable functional outcome, any ICH, HI, and PH after adjustment

Clinical Sciences

Cappellari et al General Anesthesia During Thrombectomy

8 July 2020 Stroke. 2020;51:2036–2044. DOI: 10.1161/STROKEAHA.120.028963

for unbalanced variables and models of propensity score

matching including predefined predictors; however, the

rate of sICH was similar between the groups. One model of propensity score matching showed that the rate of death was higher in the GA group. After excluding patients who started GA during the procedure, results were unchanged.

GA (versus CS) during mechanical thrombectomy was associated with lower rates of any ICH and PH after adjustment for unbalanced variables and predefined predictors; however, the rate of sICH was similar between the groups. Two models of adjustment for predefined variables showed that GA was associated also with a lower rate of HI, whereas 3 models showed that GA was associated also with a lower rate of favorable outcome.

GA (versus LA) during mechanical thrombectomy was associated with lower rates of excellent and favorable outcome, any ICH, HI, and PH after adjustment for unbalanced variables and predefined predictors; however, the rate of sICH was similar between the groups. Four models of adjustment for predefined variables showed that GA was associated also with a higher rate of death.

Our study showed that GA during thrombectomy was associated with worse functional outcomes, especially when compared with LA in line with 2 small studies^{14,15}; however, the association was not related to an increase of sICH or to a decrease of recanalization success in the GA group. Further studies are needed to identify the underlying mechanisms, such as neurotoxicity according to type and duration of GA, hemodynamic adverse effects, hypocapnic conditions, or extracranial complications during GA, which could explain the association between GA and worse functional outcome.

We are aware that our study has some limitations.

First, the present study did not randomize patients by anesthesia type, but it is based on a retrospective analysis of prospectively collected data. Second, the number

of missing data for outcome measures and predefined predictors might have influenced the final outcome.

Third, reasons for the choice of GA (versus CS or LA) were not recorded; it is likely that these choices were influenced by unmeasurable factors related to individual physician's decision, which might have influenced our key findings. Fourth, data on the type of anesthesia were not collected for the entire patient cohort. Fifth, data on duration of anesthetic exposure and intubation, type of anesthetic agent, and reasons of conversion from LA/CS to GA were not available. Finally, we did not use data of collateral circulation because they were missing in more than half of the patients included in the analyses, whereas data of other possible predictors such as the use of a balloon guide catheter were not systematically collected.

Nevertheless, to the best of our knowledge, the present study included the largest cohort of patients treated

with mechanical thrombectomy to assess whether there are differences of GA versus non-GA, GA versus CS, and GA versus LA on a complete panel of functional and radiological outcome measures after adjustment for unbalanced variables and models including predefined variables.

CONCLUSIONS

GA (versus non-GA) during mechanical thrombectomy was associated with worse functional outcomes. GA was associated with a lower rate of favorable outcome when compared with CS, whereas GA was associated with lower rates of excellent and favorable outcome and a higher rate of death when compared with LA. GA was associated with lower rates of intracerebral bleedings; however, the rate of sICH was similar among all the comparison groups. Recanalization success did not differ. Therefore, LA seems to be preferable to GA as anesthetic strategy during thrombectomy. However, the inclusion of an LA arm in future randomized clinical trials of anesthesia strategy is recommended.
